(54) Title: WEIGHT SELECTION METHODS AND APPARATUS

(57) Abstract: An exercise dumbbell (100) has at least one weight selector (160) that is rotatable into engagement with various combination of weights (227-229) at opposite ends of the handle (120). On a first embodiment, first and second weight selectors (160) are rotatably mounted on opposite ends of a bar (120) for independent rotation relative to the handle (120). On a second embodiment, first and second weight selectors (560) are keyed to a common bar (510) and rotated together therewith relative to the handle (510).

WO 03/089070 A1

WEIGHT SELECTION METHODS AND APPARATUS

Field of the Invention

5 The present invention relates to exercise equipment and more particularly, to weight selection methods and apparatus for free weights such as dumbbells and barbells.

Background of the Invention

10 Various weight selection methods and apparatus have been developed to provide adjustable resistance to exercise. With respect to free weights, weight plates are typically mounted on opposite ends of a bar. In relatively advanced systems, the bar or handle assembly is stored in proximity to the weight plates, and at least one selection mechanism is provided to connect a desired amount of mass to the bar.

15 Some examples of patented barbell/dumbbell improvements and/or features are disclosed in U.S. Pat. No. 4,529,198 to Hettick, Jr. (discloses a barbell assembly having opposite end weights that are maintained in alignment on respective storage members and selectively connected to a handle by means of axially movable springs); U.S. Pat. No. 4,822,034 to Shields (discloses both barbell and dumbbell assemblies having opposite end weights that are maintained in alignment on a shelf and selectively connected to a handle by means of latches on the weights); U.S. Pat. No. 4,284,463 to Shields (discloses a dumbbell assembly having
20 opposite end weights that are maintained in alignment on a base and selectively connected to a handle by means of cam driven pins on the weights); U.S. Pat. No. 5,637,064 to Olson et al. (discloses a dumbbell assembly having a plurality of interconnected opposite end weights that are stored in nested relationship to one another and selectively connected to a handle by means of a U-shaped pin); U.S. Pat. No. 5,769,762 to Towley, III et al. (discloses a dumbbell assembly
25 having a plurality of interconnected opposite end weights that are stored in nested relationship to one another and selectively connected to a handle by various means); U.S. Pat. No. 5,839,997 to Roth et al. (discloses a dumbbell assembly having opposite end weights that are maintained in alignment on a base and selectively connected to a handle by means of eccentric cams on a rotating selector rod); and U.S. Pat. No. 6,033,350 to Krull (discloses a dumbbell assembly
30 having opposite end weights that are maintained in alignment on a base and selectively connected to a handle by means of respective first and second selector rods that move axially in opposite directions). Despite these advances and others in the field of weight selection, room for improvement and continued innovation remains.

Summary of the Invention

The present invention provides weight selectors that occupy spaces between adjacent weights and rotate through a range of orientations to alternatively engage and disengage various combinations of the weights. Each weight selector is configured to engage any combination of
5 at least two weights. Many features and advantages of the present invention will become apparent from the more detailed description that follows.

10 Detailed Description of the Preferred Embodiment

The present invention provides methods and apparatus to facilitate adjustment of weight resistance to exercise motion. Generally speaking, the present invention allows a person to adjust weight resistance by rotating one or more weight selectors into engagement with a desired combination of weights.

15 Figure 1 shows an exercise dumbbell 100 constructed according to the principles of the present invention. The dumbbell 100 includes a handle assembly 110 and a plurality of weight plates 227-229 that are selectively connected to the handle assembly 110. As shown in Figure 2, the weight plates 227-229 rest on a weight base or cradle 300 when not in use. The base 300 is preferably an injection molded plastic member having an intermediate portion, and
20 respective weight storage areas at opposite ends of the intermediate portion. Each weight storage area is defined by a plurality of side walls, end walls, and spacers which cooperate to define discrete weight upwardly opening slots or compartments 327-329. The upper corners on these walls and spacers are preferably beveled and/or rounded to help guide the weight plates 227-229 into place. Also, each end wall 307 and 309 is preferably contoured or notched (as
25 shown in Figure 3) for reasons discussed below. The depicted base 300 does not require a bottom wall because of the manner in which the weight plates 227-229 are configured, but the present invention is not limited to such an arrangement. Some other weight storage arrangements are disclosed in U.S. Pat. No. 4,529,198 to Hettick, Jr.; U.S. Pat. No. 4,822,034 to Shields; U.S. Pat. No. 4,284,463 to Shields; U.S. Pat. No. 5,839,997 to Roth et al.; and U.S. Pat.
30 No. 6,033,350 to Krull, all of which are incorporated herein by reference.

Figures 4-6 show one group of weight plates 227-229 by themselves, though arranged as if supported by the base 300. With the exception of thickness, the weight plates 227-229 are identical to one another. The weight plates 227-229 are preferably made of steel. For the

dumbbell 100, the weight plates 227 are configured to weigh five pounds each; the weight plates 228 are configured to weigh seven and one-half pounds each; and the weight plates 229 are configured to weigh ten pounds each. Those skilled in the art will recognize that different weight amounts may be selected as a matter of design choice. In this particular case, the selected weights are deemed a desirable choice for reasons discussed below.

As shown in Figures 4-6, each of the weight plates 227-229 has an upwardly opening slot 207, and a peg or nub 208 that is disposed immediately beneath the slot 207 and protrudes orthogonally outward from the plate. The lower corners of each plate 227-229 are notched to provide a relatively narrower lower end 230, and laterally extending, downwardly facing shoulders 233 on opposite sides thereof. These notches tend to offset the impact of the slot 207 for purposes of maintaining proximity between the center of mass and the geometric center of the weight plate. Also, the narrow end 230 is configured to fit inside a respective slot 327-329 in the base 300, and the shoulders 233 are configured to rest on respective sidewalls of the base 300, thereby eliminating the need for a bottom wall. This arrangement also reduces the size of the base 300 relative to the size of the weight plates 227-229. The weight plates 227-229 preferably have rounded corners to eliminate sharp edges and to facilitate both insertion of the weight plates 227-229 into the base 300 and insertion of the handle assembly 110 into the weight plates 227-229.

The handle assembly 110 includes an intermediate hand grip or handle 120 that is shown by itself in Figures 25-26. The handle 120 is preferably an extruded plastic member that may be described as a cylindrical tube. The exterior of the handle 120 may be knurled, contoured, and/or coated to facilitate a comfortable and reliable grip. The outside diameter defined by the tube is 1.125 inches, and the inside diameter defined by the tube is 0.75 inches. A groove or keyway 122 is provided along the internal sidewall of the handle 120, and the keyway 122 extends axially the length of the handle 120 (five and one-half inches).

The handle 120 is mounted on a bar 130 that is shown by itself in Figures 22-24. The bar 130 is preferably made of steel, and may be described as a modified cylindrical rod that defines a longitudinal axis. An intermediate portion of the bar 130 is five and one-half inches long and defines an outside diameter of 0.75 inches. In other words, the handle 120 is configured to fit snugly onto the intermediate portion of the bar 130. A groove or keyway 132 extends axially along the intermediate portion of the bar 130, which is otherwise cylindrical in shape. The groove 132 in the bar 130 is similar in size and shape to the groove 122 in the handle 120, and a pin or key (not shown) is inserted through the aligned grooves 122 and 132 to

key the handle 120 against rotation relative to the bar 130. Other arrangements, including radially extending pins or screws may be used in the alternative to secure the handle 120 to the bar 130. Also, an alternative bar may be manufactured with the handle forming an integral portion thereof.

5 Opposite end portions of the bar 130 are provided with diametrically opposed flat surfaces 134 and 136. Each of the flat surfaces 134 extends axially along the entire length of a respective end portion (four and five-eighths inches), and each of the flat surfaces 136 extends only one-quarter inch inward from a respective distal end. One of the longer flat surfaces 134 is circumferentially aligned with the groove 132 and accommodates insertion of the key between
10 the handle 120 and the bar 130. The other longer flat surface 134 is diametrically opposed.

 The flat surfaces 134 and 136 on the bar 130 are configured to receive respective ends of respective brackets 140, one of which is shown by itself in Figures 18-21. Each bracket 140 is preferably a steel plate that has been bent into a U-shaped configuration, including an intermediate strip 141, an inside flange 142 having an elliptical shape, and an outside flange 145
15 having a rectangular shape. Prior to assembly of the dumbbell 100, the angles defined between the strip 141 and each of the flanges 142 and 145 are preferably slightly greater than ninety degrees for reasons discussed below.

 A generally D-shaped opening 144 extends through the inside flange 142 and is configured to fit snugly onto either end portion of the bar 130 (because the longer flat surfaces
20 134 are diametrically opposed, and the shorter flat surfaces 136 are diametrically opposed). In other words, the inside flange 142 is slidable into abutment against either end of the intermediate portion of the bar 130. An opening 146 extends through the outside flange 145 and is configured to fit snugly onto either distal end of the bar 130 and into abutment against the remainder of the end portion. As discussed below, a weight indicator 160 and three weight
25 engagement members 167-169 are mounted on each end portion of the bar 130 prior to a respective outside flange 145. The opening 146 is bounded by two diametrically opposed cylindrical surfaces and two diametrically opposed flat surfaces which cooperate to define an opening similar to the profile of the distal ends of the bar 130 (shown in Figure 23). The openings 144 and 146 cooperate with the bar 130 to key the bracket 140 against rotation relative
30 to the bar 130. Other arrangements, including welding or keying, may be used in the alternative.

 Threaded holes 138 extend into respective distal ends of the bar 130 to receive respective fasteners 108, one of which is shown by itself in Figure 27. Each fastener 108 may be described as a bolt having a threaded shaft (not shown) and a relatively larger diameter head.

A tool receiving opening 108 is preferably provided in the head of the fastener 108 to facilitate tightening of the fastener relative to the bar 130 by means of a wrench or other appropriate tool.

The fasteners 108 cooperate with the intermediate portion of the bar 130 to prevent axial movement of the brackets 140 and/or the weight engagement members 167-169. The slightly divergent configuration of the flanges 142 and 145 provides a spring washer sort of effect.

Each bracket 140 is configured to maintain the weight plates 227-229 in the same relative positions as the base 300. In this regard, the strip 141 is configured to fit inside the slots 207 in the weight plates 227-229, and three pairs of tabs 147-149 extend outward from opposite sides of the strip 141. The tabs 147 cooperate with the inside flange 142 to define a first weight slot 157 configured to accommodate the weight plate 227. The tabs 148 cooperate with the tabs 147 to define a second weight slot 158 configured to accommodate the weight plate 228. The tabs 149 cooperate with the tabs 148 to define a third weight slot 159 configured to accommodate the weight plate 229.

As noted previously, a weight indicator 160 and a group of three weight engagement members 167-169 are mounted on each end portion of the bar 130. One of the weight indicators 160 is shown by itself in Figures 10-12. Each weight indicator 160 is preferably an injection molded plastic disc. A circular hole 163 extends through the center of the indicator 160 and defines an inside diameter of slightly more than 0.75 inches. In other words, the indicator 160 is configured to be rotatably mounted on either end portion of the bar 130. Circumferentially spaced weight indicia 161 are provided on a first side of the indicator 160. The weight indicia 161 are arranged to appear one at a time through a window 143 in the inner flange 142 when the indicator 160 is properly positioned on the bar 130. Also, circumferentially spaced slits 164 are provided in an opposite, second side of the indicator 160 to facilitate a rotational link between the indicator 160 and the weight engagement members 167-169, as further discussed below.

Figures 7-9 show one of the middle weight engagement members 168 by itself. Each weight engagement member 167-169 is preferably an injection molded plastic member that includes a disc portion 181 and an orthogonally projecting hub (designated as 182 on the weight engagement member 168). The disc portion 181 is similar in size and shape to the indicator 160, but twice as thick. The hub portion 182 is concentrically aligned with the disc portion 181 and configured both to fit inside the slot 207 in a respective weight plate 227-229, and to span the thickness of a respective weight plate 227-229.

A circular hole 183 extends through both the disc portion 181 and the hub 182 and defines an inside diameter of slightly more than 0.75 inches. In other words, the weight

engagement members 167-169 are configured to be rotatably mounted on either end portion of the bar 130. Circumferentially spaced slits 184 are provided in the side of the disc portion 181 opposite the hub 182 to similarly facilitate a rotational link between the indicator 160 and the weight engagement members 167-169. In this regard, circumferentially spaced tabs 185 project outward from a distal end of the hub 182. The tabs 185 on the weight engagement member 168 are configured for insertion into the slits 184 in the adjacent weight engagement member 167. Similar tabs on the weight engagement member 167 are configured for insertion into the slits 184 in the weight indicator 160, and similar tabs on the weight engagement member 169 are configured for insertion into the slits 184 in the weight engagement member 168.

Each of the weight engagement members 167-169 has at least one lip portion that extends axially away from a radially outward portion of a respective disc portion 181. On each of the weight engagement members 167-169, the at least one lip portion spans a plurality of sectors disposed about the hub, leaving gaps in the remaining sectors. Each hub and its associated lip portion(s) cooperate to define a ring of space therebetween. This ring of space is configured to accommodate the nub 208 on a respective weight plate 227-229 when the hub is resting inside the slot 207 in the respective weight plate 227-229. In other words, the arrangement facilitates rotation of the lip portion(s) on the weight engagement members 167-169 about the nubs 208 on respective weight plates 227-229.

Each interconnected group of weight engagement members 167-169 cooperates to define a rotatable weight selector. On the dumbbell 100, each weight selector is selectively rotatable into eight different weight engaging orientations. For each of the weight engagement members 167-169, as well as the indicator 160, five of these available orientations are shown in Figures 13-17. An angle of forty-five degrees is defined between each successive orientation or sector.

In Figure 13, the "10" on the indicator 160 is positioned to appear in the window 143, and none of the weight engagement members 167-169 has a lip portion positioned to underlie or hook a respective nub 208 (at 6:00). As a result, when the handle assembly 110 is lifted from the loaded base 300 shown in Figure 2, all of the weight plates 227-229 remain at rest on the base 300. The "10" on the indicator 160 correctly indicates that the empty handle assembly 110 weighs ten pounds.

The indicator 160 and the weight engagement members 167-169 are rotated forty-five degrees counter-clockwise to arrive at the orientations shown in Figure 14. The indicator 160 now displays a "20" in the window 143, and the weight engagement member 167 has a lip

portion positioned to underlie a respective weight plate 227. With both weight engagement members 167 occupying this same orientation, both five pounds plates 227 are latched to the handle assembly 110. The "20" on the indicator 160 correctly indicates that the handle assembly 110 will now weigh twenty pounds when lifted from the base 300.

5 Figure 15 shows that the next orientation engages the seven and one-half pound plates 228 while releasing the five pound plates 227. The "25" on the indicator 160 correctly indicates that the handle assembly 110 will now weigh twenty-five pounds when lifted from the base 300.

10 Figure 16 shows that the next orientation engages the ten pound plates 229 while releasing the seven and one-half pound plates 228. The "30" on the indicator 160 correctly indicates that the handle assembly 110 will now weigh thirty pounds when lifted from the base 300.

15 Figure 17 shows that the next orientation engages both the five pounds plates 227 and the seven and one-half pound plates 228 while releasing the ten pound plates 229. The "35" on the indicator 160 correctly indicates that the handle assembly 110 will now weigh thirty-five pounds when lifted from the base 300.

20 In the next orientation (not shown), the five pound plates 227 remain engaged, the seven and one-half pound plates 228 are released, and the ten pounds plates 229 are engaged. The "40" on the indicator 160 will correctly indicate that the handle assembly 110 is set to weigh forty pounds when lifted from the base 300.

25 In the next orientation, the five pound plates 227 are released, the seven and one-half pound plates 228 are engaged, and the ten pounds plates 229 remain engaged. The "45" on the indicator 160 will correctly indicate that the handle assembly 110 is set to weigh forty-five pounds when lifted from the base 300.

30 In the last available orientation, all of the plates 227-229 are engaged, and the "55" on the indicator 160 will correctly indicate that the handle assembly 110 is set to weigh fifty-five pounds when lifted from the base 300.

As shown in Figures 7-8, the weight engagement member 168 has three circumferentially spaced lip portions 186-188, and three circumferentially spaced gaps (one of which is designated as 189). The gap 189 spans an angle B of fifty degrees, and the lip portion 187 spans an angle A of forty degrees. As suggested by this example, two and one-half degrees of added "play" or tolerance are provided on each side of each gap to reduce the possibility of "snagging" a nub 208 on a weight plate that is not supposed to be selected.

In addition to engaging a desired combination of weight plates 227-229, each weight selector cooperates with a respective bracket 140 to maintain desired axial spacing of the weight plates 227-229. In this regard, the hub 182 on the weight engagement member 168 projects axially beyond the lip portions 186-188 to an extent that is slightly greater than the thickness of a weight plate 228. In other words, the hub 182 on the weight engagement member 168 is long enough to axially span both the lip portions 186-188 and one of the weight plates 228. As a result, the weight plate 228 is slidably retained between the lip portions 186-188 on the weight engagement member 168 and the disc portion 181 on an adjacent weight engagement member 167.

The weight engagement members 167 are generally similar to the weight engagement members 168, though their hubs are shorter (because the weight plates 227 are thinner), and their lip portions are arranged differently. The weight engagement members 169 are also generally similar to the weight engagement members 168. However, in addition to having longer hubs (because the weight plates 229 are thicker), and a different arrangement of lip portions, the weight engagement members 169 are preferably configured to function as knobs, as well. As a result, the weight engagement members 169 have a relatively greater thickness, which is measured axially, and the outside flange 145 on each bracket 140 is preferably configured to facilitate access to opposite sides of a respective knob 169. The outboard flanges 145 also protect against unintended rotation of the knob 169, particularly in cases where a user chooses to rest an end of the dumbbell 100 on his/her thigh.

The outer end walls 309 on the base 300 are notched like the inner end walls 307 to provide additional access to the knobs 169 when the dumbbell 100 is resting on the base 300. The inner end walls 307 are notched to accommodate the inside flanges 142 on respective brackets 140.

Recognizing that the weight selectors rotate to latch and unlatch the weight plates 227-229 relative to the handle assembly 110, the dumbbell 100 is preferably provided with one or more mechanisms to bias and/or lock the weight selectors against unintended rotation relative to the handle assembly 110. One such arrangement is provided on each end of the dumbbell 100 in Figure 1. In particular, partially spherical depressions 119 extend into the outer surface of each knob 169 at locations spaced forty-five degrees apart from one another. A housing 116 is mounted within the upper outside corner of each bracket 140 immediately above a respective knob 169. A notch is preferably provided in the housing 116 to avoid potential interference problems with the bend in the bracket 140. In a manner known in the art, a ball is movably

mounted inside the housing 116 and allowed to project downward beyond the housing 116 and into an aligned depression 119 in the knob 169. A helical coil spring is compressed between the ball and either the overlying strip 141 on the bracket 140 or an upper portion of the housing 116. As a result of this arrangement, the knob 169 tends to click or snap into desired orientations relative to the handle assembly 110, and a threshold amount of torque is required to rotate the knob 169 out of any of these desired orientations. Other possible mechanisms include a leaf spring that deflects into and out of similar depressions, or a spring-biased lever that must first be moved to free the knob for rotation.

On the dumbbell 100, the two weight selectors operate independent of one another. In other words, the weight engagement members 167-169 at one end of the dumbbell 100 may be rotated to the orientation shown in Figure 14, while the weight engagement members 167-169 at the other end of the dumbbell 100 remain in the orientation shown in Figure 13. As a result, the opposite end weight indicators 160 will show "20" and "10", respectively, thereby correctly suggesting that the handle assembly 110 will weigh fifteen pounds (the average of ten and twenty) when lifted from the base 300. An advantage of this arrangement is that seven additional weight amounts may be selected. In other words, the dumbbell 100 provides eight different amounts of equally distributed weight, and seven additional amounts of weight that make one end of the dumbbell 100 somewhat heavier than the other end. To the extent that some people may find this imbalance undesirable, they can mitigate the effect by positioning the stronger, "thumb side" of their hand toward the heavier end, and/or adjusting their grip toward the heavier end. In any event, an advantage of the present invention is that relatively few weight plates are required to provide a relatively large number of effective dumbbell weights.

Another advantage associated with the dumbbell 100 involves the use of weight plates 227-229 that weigh five pounds, seven and one-half pounds, and ten pounds, respectively. Although the present invention is not limited in this regard, this particular combination strikes a seemingly desirable compromise between the range of available weights and the magnitude of adjustment between available weights. One alternative option is to use weight plates that weigh two and one-half pounds, five pounds, and ten pounds, respectively. Together with a ten pound handle assembly, this combination would provide a range of ten to forty-five pounds in balanced five pound increments (assuming that the lip portions on the weight engagement members were rearranged to provide proper sequential selection of the weight amounts). In other words, this option provides generally the same magnitude of adjustment increments but with a maximum weight that is ten pounds lighter than the dumbbell 100. Another option is to use weight plates

that weigh five pounds, ten pounds, and fifteen pounds, respectively. Together with a ten pound handle assembly, this combination would provide a range of ten to seventy pounds in balanced ten pound increments (again assuming that the lip portions on the weight engagement members were rearranged to provide proper sequential selection of the weight amounts). In other words, this option provides a greater maximum weight but with adjustment increments that are generally double those available with the dumbbell 100.

Many of the details associated with the dumbbell 100 may be modified or changed without departing from the scope of the present invention. Among other things, different amounts of weight, numbers of weight plates, and/or sizes of components may be substituted for those described above. This flexibility extends to the number of available weight selecting orientations, and/or choosing less than all of the possible combinations of weights. For example, the weight selectors may be reconfigured to select ten combinations of four weight plates at each end of the dumbbell, in a manner that provides smaller increments of change at the lower end of the available weight range while also providing a higher maximum weight. The following chart sets forth one possible example involving ten available amounts of balanced weight.

	Knob	Handle	1st Weights	2nd Weights	3rd Weights	4th Weights	Total
	0°	10	0	0	0	0	10
20	36°	10	5	0	0	0	15
	72°	10	0	10	0	0	20
	108°	10	5	10	0	0	25
	144°	10	0	0	20	0	30
	180°	10	0	10	20	0	40
25	216°	10	0	10	0	30	50
	252°	10	0	0	20	30	60
	288°	10	0	10	20	30	70
	324°	10	5	10	20	30	75

Another chart is set forth below to represent another desirable combination of weights. On this particular embodiment, the handle assembly is configured to weigh five pounds; the plates nearest the handle weigh six and one-quarter pounds each; the intermediate weights weigh two and one-half pounds each; and the outermost weights weigh one and one-quarter

pounds each. By arranging one weight selector to select only the heaviest weight, and the other weight selector to select only the two lighter weights (see "Split" in the chart), an effective dumbbell weight of fifteen pounds is realized, and the selected weight will feel relatively well balanced because the relative distances between the selected weights and the center of the handle tend to produce offsetting moment arms. In other words, this particular arrangement of weights may be considered advantageous because it provides a ninth, "essentially balanced" weight amount and facilitates a desirable weight range from a marketing perspective.

	Knob	Handle	1.25's	2.5's	6.25's	Total
10	0°	5	0	0	0	5.0
	45°	5	2.5	0	0	7.5
	90°	5	0	5	0	10.0
	135°	5	2.5	5	0	12.5
	Split	5	1.25	2.5	6.25	15.0
15	180°	5	0	0	12.5	17.5
	225°	5	2.5	0	12.5	20.0
	270°	5	0	5	12.5	22.5
	315°	5	2.5	5	12.5	25.0

Design flexibility exists with respect to various other elements, as well, including the location of the indicia for indicating the amount of selected weight, and/or the manner in which such indicia is provided. Also, alternative embodiments may be configured to accommodate knobs or other rotational aids in different locations, including just beyond each end of the handle, as opposed to just inside the distal ends of the dumbbell. Alternative embodiments may also include reconfigured weight engagement members which would, for example, have first and second lip portions that extend axially in opposite directions to selectively engage respective first and second weights on opposite sides of a respective weight engaging member.

Some of the possible variations of the present invention are embodied on an exercise dumbbell designated as 500 in Figure 28. This dumbbell 500 has an intermediate handle 510 that is configured for grasping, and opposite end weight housings 520 that are configured to accommodate respective weight plates 530, 540, and 550. When not in use, the weight plates 530, 540, and 550 rest on a base or cradle designated as 600 in Figures 44-46.

The handle 510 is a cylindrical tube that is preferably made of steel. The handle 510 has

a longitudinal axis and opposite ends secured to respective housings 520 (by welding or other suitable means). Each of the housings 520 includes an inside end wall 522, an outside end wall 526, a top wall 528, and opposite side walls 529, which cooperate to define a downwardly opening compartment. Figure 28 shows integrally molded housings 520, and Figure 29 shows a housing 520' which is identical in size and configuration, but assembled from three discrete parts. In either case, spacers may be provided to extend downward from the top wall 528 and occupy axial spaces between the weight plates 530, 540, and 550. Axially offset shoulders 524 are provided on interior, diametrically opposed sides of each end wall 522 and 526 to engage respective weights 530 and 550 and define centrally located gaps between the weights 530 and 550 and respective end walls 522 and 526. The shoulders 524 are disposed laterally inward from the outside edges of the walls 522 and 526.

A weight selector 560 is rotatably mounted relative to the handle 510 and/or the housings 520. The weight selector 560 includes a shaft 561 and two sets of weight engaging members or weight supports 570, 580, and 590 mounted on the shaft 561. The shaft 561 includes an intermediate portion 562 having a circular profile, and opposite end portions 563 having generally D-shaped profiles (a flat surface extends along an otherwise circular profile). The intermediate portion 562 extends through the handle 510 and through the inside end wall 522 of each housing 520. Each end portion 563 extends through a respective housing 520 and through a respective outside end wall 526.

The innermost weight support 570 is shown by itself in Figures 34-35. The support 570 includes an axially extending hub 578, a radially extending rim 576, and an axially extending lip 573. The support 570 is preferably an injection molded plastic member, and the rim 576 may be said to be integrally connected between the lip 573 and the hub 578. An opening 579 extends through the hub 578 and the rim 576, and is configured to fit snugly onto an end 563 of the shaft 561. The lip 573 includes a single, continuous segment or hook that preferably extends through an arc of 167.5°. The lip 573 spans a sector designated as Z in Figure 35, but does not span the sector designated as A.

The intermediate weight support 580 is shown by itself in Figures 36-37. The support 580 includes an axially extending hub 588, a radially extending rim 586, and an axially extending lip 584. The support 580 is preferably an injection molded plastic member, and the rim 586 may be said to be integrally connected between the lip 584 and the hub 588. An opening 589 extends through the hub 588 and the rim 586, and is configured to fit snugly onto an end 563 of the shaft 561. The lip 584 includes two diametrically opposed segments or hooks

that preferably extend through respective arcs of 77.5°. One of the segments spans the sector designated as Z in Figure 37, but neither of the segments spans the sector designated as A.

The outermost weight support 590 is shown by itself in Figures 48-49. The support 590 includes an axially extending hub 598, a radially extending rim 596, and an axially extending lip 594. The support 590 is preferably an injection molded plastic member, and the rim 596 may be said to be integrally connected between the lip 593 and the hub 598. An opening 599 extends through the hub 598 and the rim 596, and is configured to fit snugly onto an end 563 of the shaft 561. The lip 593 includes four circumferentially spaced segments or hooks that preferably extend through respective arcs of 32.5°. One of the segments spans the sector designated as Z in Figure 39, but none of the segments spans the sector designated as A.

A fastener is secured to one end 563 of the shaft 561, just beyond an adjacent, outside end wall 526 of a respective housing 520, and a knob 565 is fastened to an opposite end 563 of the shaft 561 just beyond the outside end wall 526 of the other housing 520. As shown in Figures 30-31, the knob 565 includes a relatively large diameter rim 566 that is configured for grasping, an intermediate portion 567 that bears against the outside end wall 526, and a relatively small diameter hub 568 that extends through the outside end wall 526. A recess 506 is provided in the hub 568 to receive a fastener in countersunk fashion. Both the knob 565 and both sets of supports 570, 580, and 590 are constrained to rotate together with the shaft 560 relative to the housings 520 and the handle 510. In other words, unlike the dumbbell 100, the dumbbell 500 has first and second weight selectors that are constrained to rotate together relative to the handle 510.

The weight plates 530, 540, and 550 are shown in greater detail in Figures 40-43. Although the two plates 540 and 550 are shown with the same thickness, the plate 550 weighs one-half as much as the plate 540. The plate 550 may be made from a different density material and/or may be "cored out" to achieve the difference in mass vis-a-vis the plate 540. The plate 530 is configured to weigh twice as much as the plate 540. The end views of the plate 550 shown in Figures 41 and 43 are representative of the end views of the other plates 540 and 530.

Each side of the plate 550 (and the plates 540 and 530) may be described with reference to a relatively thinner, intermediate portion 551 and relatively thicker, opposite side portions 552. The side portions 552 bear against adjacent counterparts and/or against shoulders 524 on respective end walls 522 or 526 on the housings 520. The intermediate portion 551 cooperates with adjacent counterparts and/or the end walls 522 or 526 to define gaps 545 disposed between the side portions 552 and the shoulders 524. The gaps 545 are configured to receive respective

weight engagement members 570, 580, and 590. Figure 41 shows how the weight engagement members 590, 580, and 570 axially align with the plates 550, 540, and 530.

5 An elongate slot 556 extends downward into each of the plates 550, 540, and 530, and is configured to accommodate the axial hub 598, 588, or 578 on a respective support 590, 580, or 570. Just beneath the slot 556, a nub or peg 559 projects axially outward from the intermediate portion 551 of the plate 550 (and each of the plates 540 and 530). The peg 559 is disposed just inside the path A-Z traveled by the axially extending lip 595 on the support 590. As on the dumbbell 100, when a segment of the lip 595 is disposed beneath the peg 559, the plate 550 is "hooked" or constrained to move upward together with the handle 510.

10 The upper ends of the side portions 552 terminate in respective laterally extending portions 553, which extend away from one another. The lateral portions 553 are the same thickness as the side portions 552. The lower ends 554 of the side portions 552 are beveled or tapered. Relatively thinner, triangular fins 555 extend between respective lateral portions 553 and respective side portions 552. The fins 555 are configured to fit within opposing slots 625 in the base 600, and the lateral portions 553 are designed to rest on top of the ledge 603. Similar fins 555 on the plates 540 and 530 are configured to fit within respective slots 624 and 623 in the base 600. The grooves 623-625 are bounded by inclined, opposing walls which cooperate to center the plates 530, 540, and 550 relative to the base 600. Additional grooves 622 and 626 are provided in the base 600 to receive the end walls 522 and 526, respectively. The grooves 626 are bounded by relatively outward walls which are inclined upward and away from the middle of the base 600.

25 The base 600 has a bottom 610 that is configured to rest upon a flat surface, such as a table top or floor. Opposite end portions 601 and 602 extend upward from the bottom 610. In addition to outside walls, interior walls 604 extend upward from the bottom 610 and between opposing end walls 522 on respective housings 520. Elongate slots 606 extend downward into the interior walls 604 to accommodate the handle 510. When the plates 530, 540, and 550 are suspended from the base 600, the slots 606 align with the slots 556.

30 As on the dumbbell 100, the weight selector 560 is designed for rotation in 45° increments, but as discussed above, the present invention is not strictly limited in this regard. Also, a ball detent or other biasing system may be interconnected between the housing 520 and either the knob 565 or the weight selector shaft 561, for example, to bias the weight selector 560 to enter into and remain in the desired orientations.

The lips 573, 584, and 595 are configured to provide a wide berth or an added margin of

clearance vis-a-vis the pegs 559. In particular, when any given plate 530, 540, or 550 is not engaged, the respective lip 573, 584, or 595 is at least 61 outside the boundary of the peg 559. With reference to the support 590, for example, each of the lip segments 595 spans an arc of 32.51.

5 The configurations of the weight supports 570, 580, and 590, as well as the plates 530, 540, and 550, are such that any combination of the plates 530, 540, and 550 may be secured to the handle 510 for removal from the base 600. In this regard, when the supports 570, 580, and 590 occupy the respective orientations shown in Figures 35, 37, and 39, the plates 530 are engaged to the exclusion of the plates 540 and 550. When the supports 570, 580, and 590 are rotated 1801, the sector designated as A underlies the pegs 559 on the plates 530, 540, and 550, and none is secured to the handle 510. When the supports 570, 580, and 590 are rotated until the sector designated as Z underlies the pegs 559, all of the plates 530, 540, and 550 are engaged.

15 With the handle 510 and the housings 520 designed to collectively weigh ten pounds, and the plates 530, 540, and 550 weighing ten pounds, five pounds, and two and one-half pounds, respectively, the following chart shows how different amounts of weight may be selected as a function of the orientation of the weight selector 560.

	Knob	Handle	Weights 590	Weights 580	Weights 570	Total
20	--	10	0	0	0	10
	45°	10	5	0	0	15
	90°	10	0	10	0	20
	135°	10	5	10	0	25
	180°	10	0	0	20	30
25	225°	10	5	0	10	35
	270°	10	0	10	20	40
	315°	10	5	10	20	45

30 Like the dumbbell 100, the dumbbell 500 requires only three discrete weights at each end to provide eight different balanced dumbbell loads. Unlike the dumbbell 100, balanced adjustments to the effective weight of the dumbbell 500 may be made by rotating a single knob. Although the unitary weight selector 560 does not accommodate additional, out of balance weight amounts, the number of available dumbbell loads may be doubled by selectively adding

opposite end "half-weights" that weigh one-half as much as the plates 590. For example, such half-weights could be connected to the inside end walls 522 by means of hook and loop fasteners or spring clips.

5 As noted above with respect to the dumbbell 100, several of the details concerning the dumbbell 500 may be modified without departing from the scope of the present invention. Among other things, many of the features and variations discussed above with reference to the dumbbell 100 are applicable to the dumbbell 500, and vice versa. Still another possible modification is depicted on an alternative embodiment weight engagement member designated as 770 in Figures 47-49.

10 Like the weight engagement members on the dumbbells 100 and 500, the weight engagement member 770 includes a radially extending disc portion 771, an axially extending hub portion 772, and at least one axially extending lip portion 778. As shown in Figure 49, small openings may be provided in the lip portion 778 to improve the strength-to-mass ratio of the part. A cylindrical hole 773 extends through the hub portion 772 and the disc portion 771 to
15 facilitate rotatable mounting of the weight engagement member 770 on a cylindrical shaft. Also, a groove or keyway 774 cooperates with the hole 773 to facilitate keying of the weight engagement member 770 on a cylindrical shaft (in the alternative). Circumferentially spaced leaf springs 777 are integrally formed in the disc portion 771 of the weight engagement member 770. As shown in Figure 48, the intermediate portion of each leaf spring 777 projects axially
20 beyond the disc portion 771, in a direction opposite the hub portion 772. The purpose of these springs 777 is to "take up" or span any gap between the disc portion 771 and the weight plate that may be caused due to tolerances in the manufacturing process, and/or to impose a clamping force against an adjacent weight plate. In any event, leaf springs 777 must be configured in a manner that any associated clamping and/or friction forces do not cause "unselected" weight
25 plates to rise from the base together with the handle assembly.

The present invention may also be described in terms of various methods of providing adjustable mass to resist exercise motion. Many such methods may be described with reference to the foregoing embodiments. For reasons of practicality, the foregoing description and accompanying figures are necessarily limited to only some of the many conceivable
30 embodiments and applications of the present invention. Other embodiments, improvements, and/or modifications will become apparent to those skilled in the art as a result of this disclosure. Moreover, those skilled in the art will also recognize that aspects and/or features of various methods and/or embodiments may be mixed and matched in numerous ways to arrive at

still more variations of the present invention. In view of the foregoing, the scope of the present invention is to be limited only to the extent of the following claims.

WHAT IS CLAIMED IS:

1. An adjustable mass free weight system, comprising:
a handle assembly including a hand grip, a first weight selector disposed at a first
end of said hand grip, and a second weight selector disposed at an opposite, second end of said
5 hand grip, wherein each said weight selector is rotatably connected to said hand grip, and each
said weight selector includes (a) a base portion that defines a longitudinal axis, (b) radial
portions that are affixed to said base portion at axially spaced locations and extend radially away
from said base portion, and (c) axial portions that are affixed to radially outward ends of
respective radial portions and extend axially away from respective radial portions;
10 a plurality of aligned weights, wherein slots in the weights are configured to
receive said base portion, and gaps are defined between adjacent weights to receive respective
radial portions and axial portions therebetween, and each of said weights has a nub that projects
axially toward a respective one of said radial portions and is selectively engaged when a
respective one of said axial portions is rotated beneath said nub; and
15 a base configured to support said weights in a rest position.
2. The system of claim 1, wherein each of said weights has an axially extending
shoulder that spans a respective one of said gaps.
3. The system of claim 1, wherein said first weight selector is rotatable relative to
said second weight selector.
- 20 4. The system of claim 1, wherein opposite end portions of a bar project outward
from respective ends of said hand grip, and each said base portion forms a tube about a
respective one of said end portions.
5. The system of claim 1, wherein each said base portion is keyed to a common bar
25 that extends through said hand grip.
6. The system of claim 1, wherein each said weight selector is rotatable to a first
orientation relative to said weights, wherein only first said weights at respective ends of said
hand grip are engaged by respective axial portions, and each said weight selector is rotatable to a
second orientation relative to said weights, wherein only second said weights at respective ends
30 of said hand grip are engaged by respective axial portions.
7. The system of claim 6, wherein each said weight selector is rotatable to a third
orientation relative to said weights, wherein both said first weights and said second weights are
engaged by respective axial portions.

8. The system of claim 1, wherein at least one of said radial portions supports at least two said axial portions that are circumferentially spaced apart from one another.

9. The system of claim 1, wherein at least one of said radial portions supports at least three said axial portions that are circumferentially spaced apart from one another.

5 10. The system of claim 1, wherein said weights have lower ends that are configured to fit into respective slots in said base, and transversely extending shoulders that are configured to rest on opposite sidewalls on said base.

11. An adjustable mass free weight system, comprising:

a hand grip;

10 at least one weight selector that defines a longitudinal axis and is rotatably connected to said hand grip, wherein a plurality of discrete engagement members are affixed to each said weight selector at discrete axially spaced locations, and each of said members includes a radially extending segment and at least one axially extending segment affixed to a radially outward portion of said radially extending segment;

15 a plurality of weights, wherein each of said weights has a slot that is configured to receive a respective said weight selector, and adjacent said weights define gaps therebetween to accommodate respective members, and each of said weights has an axially extending nub that is disposed radially inside a rotational path defined by each said axially extending segment on a respective one of said members, and said at least one weight selector rotates relative to said
20 weights to move each said axially extending segment into and out of underlying engagement with a respective nub; and

a base configured to support said weights in a rest position.

12. The system of claim 11, wherein said at least one weight selector is rotatable to a first orientation relative to said weights, wherein only a first one of said weights is engaged, and
25 said at least one weight selector is rotatable to a second orientation relative to said weights, wherein a second one of said weights is engaged.

13. The system of claim 12, wherein said at least one weight selector is rotatable to a third orientation relative to said weights, wherein both said first one of said weights is engaged by a respective axially extending segment, and said second one of said weights is engaged by a
30 respective axially extending segment.

14. The system of claim 11, wherein opposite end portions of a bar project outward from respective ends of said hand grip, and said at least one weight selector includes first and second weight selectors rotatably mounted on respective end portions of said bar and rotatable

independent of one another.

15. The system of claim 11, wherein said weights have lower ends that are configured to fit into respective slots in said base, and transversely extending shoulders that are configured to rest on opposite sidewalls on said base.

5 16. An adjustable mass free weight system, comprising:

a bar having an intermediate handle portion, a first end portion, and an opposite, second end portion, wherein said bar defines a longitudinal axis;

a first weight plate and a second weight plate maintained in axial alignment along said first end portion of said bar;

10 a third weight plate and a fourth weight plate maintained in axial alignment along said second portion of said bar, wherein each said weight plate includes an axially extending nub;

a first weight selector and a second weight selector, wherein each said weight selector is rotatably mounted on a respective end portion of said bar, and said first weight selector includes at least one dedicated hook for each of said first weight plate and said second weight plate, and said second weight selector includes at least one dedicated hook for each of said third weight plate and said fourth weight plate, and each said hook is configured to engage and disengage a respective said nub as a function of its orientation relative to said bar, and each said hook on said first weight selector is constrained to rotate together, and each said hook on
20 said second weight selector is constrained to rotate together; and

a base configured to support said weights in a rest position.

17. The system of claim 16, wherein a first bracket is secured to said first end portion of said bar, and a second bracket is secured to said second end portion of said bar, and each said bracket bounds a distal end of a respective weight selector.

25 18. The system of claim 16, wherein a first bracket is secured to said first end portion of said bar, and a second bracket is secured to said second end portion of said bar, and each said bracket has a U-shaped configuration with opposite distal ends connected to said bar and an intermediate portion spanning a respective weight selector.

30 19. The system of claim 16, wherein a first bracket is secured to said first end portion of said bar, and a second bracket is secured to said second end portion of said bar, and each said bracket has a U-shaped configuration with opposite distal ends connected to said bar, and a respective weight selector disposed therebetween.

20. The system of claim 16, wherein each said weight plate has a lower end that is configured to fit into a respective slot in said base, and transversely extending shoulders that are configured to rest on opposite sidewalls on said base.

21. An adjustable mass free weight system, comprising:
- 5 a handle having a first end and a second end;
a plurality of first weights maintained in axial alignment at said first end of said handle;
- a plurality of second weights maintained in axial alignment at said second end of said handle;
- 10 a base configured to support said first weights and said second weights in a rest position; and
- a first means, rotatably connected to said first end of said handle, for selectively securing said first weights to said handle and for maintaining spacing between adjacent said first weights, wherein said first means is rotatable from a first orientation, wherein only one of said
- 15 first weights is secured to said handle, to a second orientation, wherein another of said first weights is secured to said handle; and
- a second means, rotatably connected to said second end of said handle, for selectively securing said second weights to said handle and for maintaining spacing between adjacent said second weights, wherein said second means is rotatable from a first orientation,
- 20 wherein only one of said second weights is secured to said handle, to a second orientation, wherein another of said second weights is secured to said handle.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US03/11542

A. CLASSIFICATION OF SUBJECT MATTER IPC(7) : A63B 21/072, 21/08, 21/06, 21/062 US CL : 482/108, 106, 107, 97, 93, According to International Patent Classification (IPC) or to both national classification and IPC		
B. FIELDS SEARCHED Minimum documentation searched (classification system followed by classification symbols) U.S. : 482/97, 93, 98 Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)		
C. DOCUMENTS CONSIDERED TO BE RELEVANT		
Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A, P	US 6,422,979 B1 (KRULL) 23 July 2002 (23.07.2002), columns 12-13	1-21
A	US 6,186,928 B1 (CHEN) 13 February 2001 (13.02.2001), column 3, lines 10-50	1, 11, 16, 21
A	US 5,971,899 A (TOWLEY, III et al.) 26 October 1999 (26.10.1999), column 2, lines 51-67	1, 11, 16, 21
A, P	US 6,540,650 B1 (KRULL) 1 April 2003 (01.04.2003), figures 3-5, column 2, lines 13-40	1-21
<input type="checkbox"/> Further documents are listed in the continuation of Box C. <input type="checkbox"/> See patent family annex.		
* Special categories of cited documents:		
"A"	document defining the general state of the art which is not considered to be of particular relevance	"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"E"	earlier application or patent published on or after the international filing date	"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"L"	document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"O"	document referring to an oral disclosure, use, exhibition or other means	"&" document member of the same patent family
"P"	document published prior to the international filing date but later than the priority date claimed	
Date of the actual completion of the international search 11 July 2003 (11.07.2003)		Date of mailing of the international search report 11 AUG 2003
